[TITLE OF THE INVENTION] WORK COMFORT EVALUATING APPARATUS  
AND WORK COMFORT EVALUATING METHOD

[CLAIMS]

[Claim 1]

A work comfort evaluating apparatus for evaluating a degree of work comfort by measuring myoelectric potentials during a work activity which is performed antagonistically by a pair of muscles provided in a human body in bilaterally symmetrical relation, the apparatus comprising:

a pair of detection sensors for detecting the myoelectric potentials produced by actions of the pair of muscles provided in the human body in bilaterally symmetrical relation during the work activity;

an amplifier for amplifying the pair of myoelectric potentials detected by the detection sensors;

a waveform processing unit for generating a synchronous contraction waveform of the pair of muscles from time-series waveforms of the pair of amplified myoelectric potentials;  
and

an evaluation unit for evaluating a level of the degree of comfort of the work activity from intensity information of the generated synchronous contraction waveform or from frequency information of the generated synchronous contraction waveform contained in a specified intensity range.

[Claim 2]

The work comfort evaluating apparatus according to claim 1, wherein the evaluation unit calculates the intensity information of the generated synchronous contraction waveform or the frequency information of the generated synchronous contraction waveform at specified time intervals and evaluates the level of the degree of comfort of the work

activity at the specified time intervals based on results of the calculation.

[Claim 3]

The work comfort evaluating apparatus according to claim 1 or 2, wherein the waveform processing unit performs full-wave rectification with respect to the time-series waveforms of the pair of myoelectric potentials, and thereafter, designates the smaller one of respective values at the same time of the time-series waveforms of the pair of myoelectric potentials that have been subjected to the full-wave rectification as a signal value of the synchronous contraction waveform.

[Claim 4]

The work comfort evaluating apparatus according to claim 1 or 2, wherein the waveform processing unit designates a geometric mean value of signal values of the time-series waveforms of the pair of myoelectric potentials as a signal value of the synchronous contraction waveform.

[Claim 5]

The work comfort evaluating apparatus according to any one of claims 1 to 4, wherein the work activity comprises steering of a wheel in driving a vehicle.

[Claim 6]

The work comfort evaluating apparatus according to claim 5, wherein the pair of muscles comprise deltoid muscles positioned in shoulders of the human body.

[Claim 7]

A work comfort evaluating method of evaluating a degree of work comfort by measuring myoelectric potentials during a work activity which is performed antagonistically by a pair of muscles provided in a human body in bilaterally symmetrical relation, the method comprising:

a step of detecting the myoelectric potentials produced by actions of the pair of muscles provided in the human body in bilaterally symmetrical relation during the work activity and amplifying the pair of myoelectric potentials;

a step of generating a synchronous contraction waveform of the pair of muscles from time-series waveforms of the pair of amplified myoelectric potentials; and

a step of evaluating a level of the degree of comfort of the work activity from intensity information of the generated synchronous contraction waveform or from frequency information of the generated synchronous contraction waveform of the generated synchronous contraction waveform contained in a specified intensity range.

[DETAILED DESCRIPTION OF THE INVENTION]

[0001]

[Technical Field of the Invention]

The present invention relates to a work comfort evaluating apparatus and a work comfort evaluating method of evaluating a degree of work comfort by measuring a myoelectric potential during a work activity which is performed antagonistically by a pair of muscles (carnes) provided in a human body in bilaterally symmetrical relation and, more particularly, to an apparatus and method of evaluating a degree of comfort of, e.g., wheel steering when a driver steers a vehicle wheel.

[0002]

[Prior Art]

To provide a vehicle such as an automobile and a tire which allow comfort wheel steering, automobile makers and tire makers in these days have investigated the wheel steering comfort of a vehicle and performed the development of vehicles and tires by using various methods.

In the development of vehicles and tires, when it is evaluated whether or not the steering of a wheel is comfort, the evaluation is generally performed in most cases by using subjective judgment by a driver or quantitatively measuring the behavior of a vehicle by providing the vehicle with a measurement sensor for an acceleration rate or the like and acquiring physical measurement data representing the behavior of the vehicle.

[0003]

To evaluate the degree of load placed by a given work activity while it is performed, it has also been performed in these days to acquire an electromyogram representing the waveform of a myoelectric potential from an activity worker and thereby quantitatively recognize the load on the muscle of the activity worker. It is considered that the myoelectric potential enables proper evaluation of the degree of load placed by a given work activity while it is performed since the myoelectric potential can be measured easily and conveniently and is also high in responsivity. It can also be considered to apply a method of evaluating a degree of load placed by a work activity which uses the electromyogram to the steering of a vehicle wheel by a driver.

[0004]

[Problems to be Solved by the Invention]

However, since the steering of the vehicle wheel by the driver is a work activity which is performed antagonistically by deltoid muscles which are a pair of muscles provided in a human body in bilaterally symmetrical relation, the fact is that the one of the muscles on which less load is placed does not always correspond to a higher degree of comfort during wheel steering.

For example, when a force for wheel steering is small, the load on the muscles of the driver is reduced but the

problem is encountered that the steering wheel should be held incessantly with the small force. When the force for wheel steering is large, the load on the muscles when the driver steers the wheel is increased but the necessity to constantly hold the steering wheel is reduced because the wheel is stable.

Accordingly, the degree of comfort of wheel steering cannot be evaluated properly from an index of load on a muscle obtained through the measurement of an electromyogram.

[0005]

There is also a method which measures the fluctuations of the electroencephalogram, the fluctuations of the heart rate, the blood pressure, and the like as the bio-information of the driver. In either case, however, it is necessary to give a specified restriction to the driver, such as the retention of constant breathing, so a problem of placing extra burden on the driver is encountered. In addition, such bio-information has a problem in that it requires a sufficiently long measurement period in terms of analysis performed as a post process and a result which is high in responsivity cannot be obtained. Accordingly, the degree of comfort of actual wheel steering cannot be evaluated properly.

Such problems are not limited to the steering of a vehicle wheel and similarly occur in the case where the degree of work comfort is evaluated when a pair of muscles provided in a human body in bilaterally symmetrical relation antagonistically perform a work activity.

[0006]

In view of the foregoing, it is therefore an object of the present invention to provide a work comfort evaluating apparatus for evaluating a degree of work comfort by measuring a myogenic action during a work activity which is

performed antagonistically by a pair of muscles provided in a human body in bilaterally symmetrical configuration and provide a work comfort evaluating apparatus and a work comfort evaluating method which allow the evaluation of the degree of comfort of a work activity from the result of short-period measurement without imposing a restriction on an activity worker.

[0007]

[Means to Solve the Problems]

In order to achieve the above object, according to the present invention, there is provided a work comfort evaluating apparatus for evaluating a degree of work comfort by measuring myoelectric potentials during a work activity which is performed antagonistically by a pair of muscles provided in a human body in bilaterally symmetrical relation, the apparatus including:

- a pair of detection sensors for detecting the myoelectric potentials produced by actions of the pair of muscles provided in the human body in bilaterally symmetrical relation during the work activity;

- an amplifier for amplifying the pair of myoelectric potentials detected by the detection sensors;

- a waveform processing unit for generating a synchronous contraction waveform of the pair of muscles from time-series waveforms of the pair of amplified myoelectric potentials;
- and

- an evaluation unit for evaluating a level of the degree of comfort of the work activity from intensity information of the generated synchronous contraction waveform or from frequency information of the generated synchronous contraction waveform contained in a specified intensity range.

[0008]

At this time, it is preferable that the evaluation unit calculate the intensity information of the generated synchronous contraction waveform or the frequency information of the generated synchronous contraction waveform at specified time intervals and evaluates the level of the degree of comfort of the work activity at the specified time intervals based on results of the calculation.

Further, it is preferable that the waveform processing unit perform full-wave rectification with respect to the time-series waveforms of the pair of myoelectric potentials, and thereafter, designate the smaller one of respective values at the same time of the time-series waveforms of the pair of myoelectric potentials as a signal value of the synchronous contraction waveform. Alternatively, it is also preferable that the waveform processing unit designate a geometric mean value of signal values of the time-series waveforms of the pair of myoelectric potentials as a signal value of the synchronous contraction waveform.

[0009]

The work activity is exemplified by steering of a wheel in driving a vehicle. In this case, the pair of muscles are exemplified by deltoid muscles positioned in shoulders of the human body.

[0010]

Further, according to the present invention, there is provided a work comfort evaluating method of evaluating a degree of work comfort by measuring myoelectric potentials during a work activity which is performed antagonistically by a pair of muscles provided in a human body in bilaterally symmetrical relation, the method including:

a step of detecting the myoelectric potentials produced by actions of the pair of muscles provided in the human body

in bilaterally symmetrical relation during the work activity and amplifying the pair of myoelectric potentials;

a step of generating a synchronous contraction waveform of the pair of muscles from time-series waveforms of the pair of amplified myoelectric potentials; and

a step of evaluating a level of the degree of comfort of the work activity from intensity information of the generated synchronous contraction waveform or from frequency information of the generated synchronous contraction waveform contained in a specified intensity range.

[0011]

[Embodiment of the Invention]

A detailed description will be given herein below to a work comfort evaluating apparatus and a work comfort evaluating method according to the present invention based on a preferred embodiment shown in the accompanying drawings.

[0012]

FIG. 1 is a schematic structural view of a steering comfort evaluating apparatus 10 obtained by applying the work comfort evaluating apparatus according to the present invention to the wheel steering operation of a driver.

The steering comfort evaluating apparatus 10 is an apparatus for evaluating a degree of comfort of wheel steering by a driver who is driving a vehicle and is comprised of detection sensors 12 and 14 for detecting myoelectric potentials at the left and right deltoid muscles of the driver, an electrode 16, an amplifier 18 for amplifying the myoelectric potentials from the detection sensors 12 and 14, a processing unit 20 for evaluating the degree of comfort of wheel steering from the time-series waveforms of the amplified myoelectric potentials of the left and right deltoid muscles, and a monitor 22 for monitor displaying the result of evaluation.

[0013]

The detection sensor 12 is a sensor for detecting a myoelectric potential at the deltoid muscle of the left shoulder of the driver and is composed of a pair of skin surface electrodes (e.g., Ag/AgCl plate-like electrodes, Ag electrodes, or stainless steel electrodes). The pair of skin surface electrodes are attached to the surface of the left shoulder in which the deltoid muscle is positioned in spaced apart relation each other at a given distance, e.g., 2 cm.

The detection sensor 14 is a sensor for detecting a myoelectric potential at the deltoid muscle of the right shoulder of the driver and is composed of a pair of skin surface electrodes, similarly to the detection sensor 12. The pair of skin surface electrodes are attached to the surface of the right shoulder in which the deltoid muscle is positioned in spaced apart relation each other at a given distance, e.g., 2 cm.

The attachment of the detection sensors to the surface of the skin of the driver is performed by rubbing the skin surface by using a scrub, removing contamination therefrom by using alcohol, and using an electrode glue. At this time, contamination is removed until electric resistance reaches a value of 30 k $\Omega$  or less (preferably, 5 k $\Omega$ ). The two electrodes are attached to the bellies of the muscles to be measured in parallel relation to the muscle fibers. The positions of attachment are determined to avoid innervative areas so that, as shown in FIG. 2, each of the two electrodes is attached to the position P spaced apart in a longitudinal direction of the arm from the edge portion A of the acromion by the widths of three fingers to have a given distance therebetween.

[0014]

On the other hand, the electrode 16 is an earth electrode attached to the earlobe of the driver, which is an electrically inactive position, to maintain the potential of the driver constant. The electrode 16 is provided to perform precise measurement using the detection sensors 12 and 14. The electrode 16 connected to the amplifier 18 is earthed via the amplifier 18.

The amplifier 18 is a well-known operational amplifier for amplifying the myoelectric potentials detected by the detection sensors 12 and 14.

The myoelectric potentials detected by the detection sensors 12 and 14 and amplified are sent to the processing unit 20.

[0015]

The processing unit 20 is comprised of a waveform processing unit 24 and a comfort evaluation unit 26.

The processing unit 20 is a unit composed of a computer, while the waveform processing unit 24 and the comfort evaluation unit 26 are constituted to perform individual functions by executing programs.

Each of the waveform processing unit 24 and the comfort evaluation unit 26 may also be composed of a dedicated circuit.

[0016]

The waveform processing unit 24 is a portion which samples the time-series waveforms of the myoelectric potentials, performs full-wave rectification, and then normalizes each of the time-series waveforms of the myoelectric potentials by using a maximum myoelectric potential preliminarily measured by using the detection sensors 12 and 14 and recorded/held to calculate an index (Index), while outputting, as a synchronous contraction waveform, a waveform generated by selecting the smaller one

of the values of indices at the same time calculated by normalizing the myoelectric potentials of the pair of left and right deltoid muscles. The synchronous contraction waveform will be described later.

[0017]

The maximum myoelectric potential used herein is a myoelectric potential when the driver places maximum load on the deltoid muscles to cause a muscle action. The measurement of the maximum myoelectric potential is performed every time the detection sensors 12 and 14 are attached. The reason for normalizing each of the time-series waveforms of the myoelectric potentials by using the maximum myoelectric potential is that the electric resistance of each of the detection sensors 12 and 14 slightly changes every time the detection sensors 12 and 14 are attached and the magnitudes of the detected myoelectric potentials change accordingly.

The waveform processing unit 24 may also be constituted to generate a synchronous contraction waveform which uses a geometric mean value of the signal values of the pair of myoelectric potentials at the left and right deltoid muscles as a signal value. In this case, it is unnecessary to make an adjustment by normalizing each of the time-series waveforms of the left and right myoelectric potentials by using the maximum myoelectric potential so that the measurement of the maximum myoelectric potential is not required.

[0018]

The comfort evaluation unit 26 is a portion which calculates intensity information from the synchronous contraction waveform generated in the waveform processing unit 24 at specified time intervals and evaluates the level of the degree of comfort of wheel steering by the driver from the result of the calculation.

The intensity information of the synchronous contraction waveform indicates herein, e.g., the RMS (root means square) value (effective value) or integral value of the synchronous contraction waveform which is calculated at intervals of, e.g., 0.1 to 0.5 seconds, an integral value of the envelope of the synchronous contraction waveform, or the like.

Instead of calculating the intensity information of the synchronous contraction waveform, it is also possible to calculate the frequency information of the synchronous contraction waveform and evaluate the degree of comfort of wheel steering based on the frequency information. The frequency information of the synchronous contraction waveform indicates, e.g., the probability or number of times of the signal value of the synchronous contraction waveform which falls within a specified range of RMS values or the like.

[0019]

The comfort evaluation unit 26 evaluates the level of the degree of comfort of wheel steering by the driver by, e.g., comparing the RMS value of the synchronous contraction waveform with the set value of each of levels that has been predetermined for the level classification of the degrees of comfort of wheel steering by the driver. Alternatively, the comfort evaluation unit 26 evaluates the level of the degree of comfort of wheel steering by the driver by, e.g., comparing the frequency information of the synchronous contraction waveform with the set probability of each of levels that has been predetermined for the level classification of the degrees of comfort of wheel steering by the driver.

Such a result of evaluation is sent to the monitor 22 together with the synchronous contraction waveforms and the time-series waveforms of the myoelectric potentials of the left and right deltoid muscles to be displayed thereon.

[0020]

Thus, the steering comfort evaluating apparatus 10 is characterized in that it generates the synchronous contraction waveform from the time-series waveforms of the myoelectric potentials at the left and right deltoid muscles and evaluates the degree of comfort of wheel steering by the driver by using the intensity information or frequency information of the synchronous contraction waveform.

In general, the steering of a wheel by a driver is performed by the action of steering a vehicle wheel (steer). In the case of turning the vehicle to the right, e.g., the steering of the wheel involves the upward movement of the left hand holding the steering wheel so that the deltoid muscle in the left shoulder of the driver is contracted. On the other hand, the right hand only performs a helping function by touching the wheel so that the deltoid muscle in the right shoulder of the driver is slackened. In the case of turning the vehicle to the left, the deltoid muscle in the left shoulder of the driver is slackened, while the deltoid muscle in the right shoulder of the driver is contracted. The wheel steering by the driver which is performed by thus contracting one of the pair of deltoid muscles provided in a human body in bilaterally symmetrical relation and slackening the other of the pair of deltoid muscles corresponds to a work activity which is performed antagonistically by a pair of muscles provided in the human body in bilaterally symmetrical relation according to the present invention.

[0021]

However, when extra tension is placed on the hands of the driver gripping the steering wheel due to any mental load or the like or when the driver tenses up because the steering of the wheel is difficult, the pair of left and right deltoid muscles are contracted in synchronism even during the

steering of the wheel which is performed antagonistically by the pair of left and right deltoid muscles. The waveform of the myoelectric potential measured at this time is referred to as a synchronous contraction waveform.

Through such contraction of the deltoid muscles, the driver can obtain a force to hold the steering wheel. However, the force to hold the steering wheel in this case is information which cannot be obtained in the form of physical measurement data representing the behavior of the vehicle, such as an acceleration rate, by providing a measurement sensor such as a load cell.

The inventors of the present invention have found that the ease of wheel steering and the ease of control through wheel steering can be evaluated based on the intensity or frequency of the synchronous contraction and achieved the present invention.

[0022]

In the case of evaluating the degree of comfort of wheel steering by using such a steering comfort evaluating apparatus 10, the detection sensors 12 and 14 are attached initially to the surfaces of the right and left shoulders in which the deltoid muscles are positioned, as shown in FIG. 3 (Step 100). At the same time, the electrode 16 is attached to the earlobe.

After the detection sensors 12 and 14 are attached, the maximum myoelectric potential when the driver maximally contracts both the left and right deltoid muscles is measured (Step 102). The maximum myoelectric potential is sent to the waveform processing unit 24 via the amplifier 18 and recorded/held therein. As a result, it becomes possible to normalize each of the myoelectric potentials measured thereafter and hold the myoelectric potential information

constant which, otherwise, varies every time the detection sensors 12 and 14 are attached.

[0023]

Then, the driving of the vehicle by the driver is initiated, the wheel steering by the driver is performed, and the myoelectric potentials of the left and right deltoid muscles of the driver are measured constantly (Step 104).

In the measurement of the myoelectric potentials, the myoelectric potentials are amplified by the amplifier 18 and then supplied to the waveform processing unit 24.

In the waveform processing unit 24, each of the time-series waveforms of the myoelectric potentials of the left and right deltoid muscles is subjected to full-wave rectification such that a signal waveform in which each value is not less than 0 is generated. Thereafter, each of the time-series waveforms of the myoelectric potentials that have been subjected to the full-wave rectification is normalized by using the maximum myoelectric potential that has been recorded/held. Further, the smaller one of the two values of the time-series waveforms at the same time that have been subjected to full-wave rectification is designated as the signal value of the synchronous contraction waveform, whereby the synchronous contraction waveform is generated (Step 106). By thus selecting information on the myoelectric potential produced in that one of the deltoid muscles which is closer to the slackened state in the work activity of wheel steering performed antagonistically by the pair of deltoid muscles, information on the myoelectric potential when the deltoid muscles are contracted in synchronism can be obtained.

[0024]

In the comfort evaluation unit 26, the RMS values of the generated synchronous contraction waveform are calculated one after another at specified time intervals of, e.g., 0.1 to

0.5 seconds (step 108) and compared with the set value of each of the levels predetermined for the level classification of the degrees of comfort, whereby the degrees of comfort in the wheel steering by the driver are evaluated one after another (Step 110).

By thus measuring myoelectric potentials during the steering of a wheel which is performed antagonistically by a pair of deltoid muscles provided in a human body in bilaterally symmetrical relation, the degree of comfort of wheel steering by the driver which varies from moment to moment during wheel steering is evaluated from the result of short-period measurement without imposing a restriction on the driver.

[0025]

FIGS. 4(a) to 4(d) show examples of various time waveforms when the method described above is implemented. FIG. 4(a) shows an example of the time-series waveform of the angle of wheel steering performed by the driver. FIGS. 4(b) and 4(c) show an example of the time-series waveforms of the myoelectric potentials (the index (Index) obtained by calculating the ratio between the time-series waveforms and the maximum myoelectric potential) at both the left and right deltoid muscles of the driver when the wheel steering shown in FIG. 4(a) is performed, which has been subjected to full-wave rectification. FIG. 4(d) shows an example of a synchronous contraction waveform (Index) generated from the time-series waveforms of the myoelectric potentials shown in FIGS. 4(b) and 4(c).

[0026]

In this case, as can be seen from the time-series waveform of the steering angle shown in FIG. 4(a), the driver performed the steering of the wheel for a lane change at a maximum steering angle of about 20 to 30 degrees twice.

In FIG. 4(a), a positive steering angle indicates a state in which the wheel is steered to the right and a negative steering angle indicates a state in which the wheel is steered to the left. In the case of steering the wheel to the right, therefore, the contraction of the left deltoid muscle is significant as shown in FIG. 4(c). By contrast, a myoelectric potential is barely produced in the right deltoid muscle as shown in FIG. 4(b), which indicates that the right deltoid muscle is in a slackened state or in a state close to the slackened state.

In the case of turning to the right, therefore, the waveform shown in FIG. 4(c) is generally selected as the synchronous contraction waveform. Likewise, the waveform shown in FIG. 4(b) is generally selected in the case of turning to the left.

[0027]

From the generated synchronous contraction waveform shown in FIG. 4(d), the RMS values of the waveform are calculated one after another at specified time intervals and compared with the set value of each of the levels predetermined for the level classification of the degrees of comfort of the wheel steering by the driver, whereby the degree of comfort of the wheel steering by the driver is evaluated.

[0028]

FIG. 5 shows the result of calculating the RMS values of the synchronous contraction waveforms acquired under the three conditions of US (Under-Steer), OS (Over-Steer), and NS (Neutral-Steer) that have been set as the turning characteristics of a vehicle. As shown in FIG. 4(e), the RMS values of the synchronous contraction waveforms acquired under the individual conditions were calculated in a divided manner in correspondence to the steering angles.

The region  $S_a$  is a region where the steering angle is 0. The region  $L_1$  is a region where the steering angle is positive and increases with time. The region  $L_2$  is a region where the steering angle is positive and decreases with time. The region  $L_3$  is a region where the steering angle is negative and the absolute value thereof increases with time. The region  $L_4$  is a region where the steering angle is negative and the absolute value thereof decreases with time. The region  $S_b$  is a region where the steering angle is 0. The region  $L_5$  is a region where the steering angle is negative and the absolute value thereof increases with time. The region  $L_6$  is a region where the steering angle is negative and the absolute value thereof decreases with time. The region  $L_7$  is a region where the steering angle is positive and increases with time. The region  $L_8$  is a region where the steering angle is positive and decreases with time. The region  $S_c$  is a region where the steering angle is 0.

[0029]

The RMS values in the individual regions were calculated by repeating the steering of the wheel shown in FIG. 4(a) five times under each of the US, OS, and NS conditions and subjected to the analysis of variance so that it was examined whether or not the RMS values had statistically significant differences among the US, OS, and NS.

On the other hand, the driver who performed the steering of the wheel was requested to perform subjective judgment on the degree of wheel steering. According to the result of the judgment, the steering of the wheel was performed most comfortably under the NS and next most comfortably under the US.

The US is one of the turning properties of a vehicle with which, when the vehicle in the state of running along an arcuate configuration while maintaining a given steering

angle increases the driving speed thereof, the running of the vehicle expands outwardly from the above-mentioned arcuate configuration so that the turning radius is increased.

The OS is one of the turning properties of the vehicle with which, when the vehicle in the state of running along an arcuate configuration while maintaining a given steering angle increases the driving speed thereof, the running of the vehicle moves inwardly from the above-mentioned arcuate configuration so that the turning radius is reduced.

The NS is one of the turning properties of the vehicle with which, even when the vehicle in the state of running along an arcuate configuration while maintaining a given steering angle increases the driving speed thereof, the running of the vehicle does not deviate from the above-mentioned arcuate configuration so that the turning radius remains unchanged.

[0030]

FIG. 5 shows the average value of the RMS (Index) values in the regions  $S_a$ ,  $L_1$ ,  $L_2$ , ..., and  $S_c$  under each of the OS, US, and NS.

FIG. 6 shows the result of the analysis of variance on a 5% significant level performed by using the calculated RMS values. In FIG. 6, each of "<" and ">" represents the magnitude relationship between a comparison pair having a statistically significant difference therebetween.

By the result shown in FIG. 6, it was proved that the RMS value under the NS was smaller than the RMS value under the OS in each of the regions  $L_1$ ,  $L_3$ , and  $L_7$ , the RMS value under the NS was smaller than the RMS value under the US in each of the regions  $L_1$ ,  $L_4$ , and  $L_7$ , and the RMS value under the US was smaller than the RMS value under the OS in each of the regions  $L_3$  and  $L_6$ .

This has proved that the RMS value of the synchronous contraction waveform under the NS is smaller than the RMS values under the US and the OS in each of the regions (regions L<sub>1</sub>, L<sub>3</sub>, L<sub>4</sub>, and L<sub>7</sub>) where the RMS value under the NS has statistically significant differences between itself and the RMS values under the US and the OS and that the RMS value under the US is smaller than the RMS value under the OS in each of the regions (L<sub>3</sub> and L<sub>6</sub>) where the RMS values under the US and the OS has statistically significant differences therebetween.

[0031]

The result of the analysis of variance corresponds to the above-mentioned subjective judgment of the degree of comfort of wheel steering by the driver.

Accordingly, it will be understood that the use of the intensity information of the synchronous contraction waveform allows proper evaluation of the degree of comfort of the wheel steering.

It can therefore be said that the use of frequency information contained in a specified intensity range in the synchronous contraction waveform allows proper evaluation of the degree of comfort of wheel steering.

Since the RMS values vary with time, as shown in FIG. 5, the calculation of RMS values at specified time intervals further allows the evaluation of the degree of comfort which varies with time. For example, even under the NS which is the best in the degree of comfort among the US, the OS, and the NS, a region in which the RMS value increases and the degree of comfort deteriorates can be determined. This helps the development of a vehicle and a tire which investigate wheel steering comfort.

[0032]

Although the above-mentioned example has described the case where the degree of comfort is evaluated when a driver drives a vehicle and steers a wheel, the present invention does not limit the evaluation target of the degree of comfort to the steering of a wheel. The evaluation target may be any work activity provided that it is performed antagonistically by a pair of muscles provided in a human body in bilaterally symmetrical relation.

[0033]

Although the work comfort evaluating apparatus and the work comfort evaluating method according to the present invention have been described in detail, the present invention is not limited to the embodiment described above. It will be appreciated that various changes and modifications can be made in the invention without departing from the gist thereof.

[0034]

[Effects of the Invention]

As described above, the present invention measures myoelectric potentials during a work activity which is performed antagonistically by a pair of muscles provided in a human body in bilaterally symmetrical relation, generates a synchronous contraction waveform from the pair of muscles, and evaluates the level of the degree of work comfort from the intensity information or frequency information of the generated synchronous contraction waveform. This allows the evaluation of the degree of comfort of a work activity from the result of short-period measurement without imposing a restriction on, e.g., the breathing of an activity worker as has been imposed conventionally.

[TYPE OF THE DOCUMENT] Abstract

[ABSTRACT]

[Subject] The work comfort evaluating apparatus for evaluating a degree of work comfort by measuring actions of muscles during a work activity which is performed antagonistically by a pair of muscles provided in a human body in bilaterally symmetrical relation, and the degree of comfort of the work activity is evaluated from a result of short-period measurement without imposing a restriction of an activity worker.

[Means for Solution] The steering comfort evaluating apparatus 10 includes a pair of detection sensors 12 and 14 for detecting myoelectric potentials at a pair of deltoid muscles of a driver provided in a bilaterally symmetric relation produced by actions of the muscles during wheel steering, an amplifier 18 for amplifying the myoelectric potentials of the pair of deltoid muscles detected by the detection sensors 12 and 14, a waveform processing unit 24 for generating a synchronous contraction waveform of the pair of deltoid muscles from time-series waveforms of the pair of amplified myoelectric potentials, and a comfort evaluation unit 26 for evaluating a level of the degree of comfort of wheel steering from intensity information of the generated synchronous contraction waveform or from frequency information of the generated synchronous contraction waveform contained in a specified intensity range.
